

PSET 5

Izd3

1.

slots

Advertiser	A(7)	B(9)	C(3)
x(4)	28	36	8
y(2)	14	18	4
z(1)	7	9	2

advertiser x gets B = 36

advertiser y gets A = 14

advertiser z gets C = 2

a)

b)

In this case, since there are three spaces and three promoters, each advertiser gets a space in

any case. Hence, no advertiser causes any hurt to others by partaking in the sell-off. Hence, all advertisers pay a cost of zero in this VCG Method.

2.

a)

Buyer Y would win the auction and will pay the price of 8

b.)

- Buyer y takes A 10

Prices:

- Buyer y: =8
- Buyer x and z does not receive any items

If y wasn't in the auction, the item would have gone to x who would pay 8, so y pays the harm which would be 8.

3.)

	Slots		
	A	B ^a	C ^y
W	10	4	2
X	7	8	6
Y	1	3	5
Z	4	4	4

$$A_w = (4 + 5 + 8) - (8 + 5 + 10) = 4$$

$$B_x = (10 + 5 + 4) - (10 + 5) = 4$$

$$C_y = (10 + 8 + 4) - (10 + 8) = 4$$

a.)

b.)

These prices are similar because they all do equally as much harm, the true culprit of this however is buy z which has a value of 4 across all the items, so whenever we take the harm

price z always ends up making all the values go to 4

4.

a)

- X will take slot A at 25
- Y will take slot B at 12
- Z will take Slot C at 6

Prices:

- Advertiser x pays $(15+8)-(12+6)=23-18=5$
- Advertiser y pays $(25+8)-(25+6)=33-31=2$
- Advertiser z pays $(25+12)-(25+12)=37-37=0$

b.)

1. Advertiser w would be assigned to slot D as it causes the least amount of harm

Advertiser x cannot precisely determine the value of v based on the information provided. Advertiser x knows that advertiser w has the smallest value per click but doesn't have enough information to determine the exact value. Advertiser x only knows they are paying 3 more for slot a compared to their initial allocation in part (a), but this doesn't provide enough information to deduce the precise value of v .

5.)

a)

In this generalized second price auction, it is not a Nash equilibrium for each advertiser to bid their true value per click. Let's consider the bids as described:

- Advertiser x bids 10 per click.
- Advertiser y bids 9 per click.
- Advertiser z bids 6 per click.

So, it is a Nash equilibrium as each advertiser has no benefit from deviating from bidding their true value. X has the highest bid value possible so in essence, they would always bid their max as they are guaranteed to win and pay a price lower than their true value. Y should always bid 9 as it's guaranteed to at least pay the third highest bid, they would only lose or win by 1 when competing with x but if they obtain slot B, they would be making a profit of 3 guaranteed from Z.

b.)

No, it is not a Nash equilibrium because:

- Advertiser x can benefit from deviating and bidding 10 per click instead of 9. This way, they will still get slot A but pay a lower price (6 per click), increasing their utility

c.)

it is a Nash equilibrium because:

- Advertiser x cannot benefit from deviating. Bidding higher would increase their cost, and they cannot secure a better slot (they already have slot a).
- Advertiser y cannot benefit from deviating. Bidding higher would increase their cost, and they cannot secure a better slot (they already have slot b).
- Advertiser z cannot benefit from deviating. Bidding higher would increase their cost, and they cannot secure a better slot (they already have slot c).

In this case, no advertiser can improve their outcome by deviating, so the proposed bids form a Nash equilibrium.
